

## Homework #3

Indra Ratna

### Question 1

- 1.1 The worst case run time of `reverse1(lst)` is  $O(n^2)$  because the `insert` function is being called multiple times within a while loop and a while loop is running at  $O(n)$ . When being called once, `insert` function has a run time of  $O(n)$  but on multiple calls its worst run time is  $O(n^2)$ .
- 1.2 The worst case run time of `reverse2(lst)` is  $O(n)$  because multiple calls to `append` have a run time of  $O(n)$  and the while loop has a run time of  $O(n)$ . So the worst run time is  $O(n)$
- 3.B The worst case run time of `find_duplicates(lst)` is  $O(n)$  because it uses a for loop at  $O(n)$  and `sort` at  $O(n)$  with multiple uses of `append` running at  $O(n)$ , the overall worst case stands at  $O(n)$ .
- 4.A The worst case run time of `remove_all(lst, value)` is  $O(n^2)$  because within the while loop, `.remove()` is called multiple times. On multiple calls the `.remove()` function runs at  $O(n^2)$
- 4.C The worst run time of my implementation of `remove_all` in (b) is  $O(n \log n)$  because each value of `lst` is checked for whether or not it matches the value and then sliced back into the original list.
